## SYSTEMS AND METHODS FOR CHANNEL TARGET BASED CBD ESTIMATION

### CROSS REFERENCE TO RELATED APPLICATIONS

The present application is a continuation of U.S. patent application Ser. No. 13/551,507 entitled "Systems and Methods for Channel Target Based CBD Estimation", and filed Jul. 17, 2012 by Jin et al. The entirety of the aforementioned reference is incorporated herein by reference for all purposes.

### BACKGROUND OF THE INVENTION

The present inventions are related to systems and methods for processing data, and more particularly to systems and methods for channel bit density estimation.

Channels are calibrated to assure acceptable data transfer and processing characteristics. Various calibrations rely on channel bit density information. As an example, channel bit density may be optimized based upon the channel bit density information. Such channel bit density information, however, can be difficult and costly to estimate accurately.

Hence, for at least the aforementioned reasons, there exists a need in the art for advanced systems and methods for data processing.

### BRIEF SUMMARY OF THE INVENTION

The present inventions are related to systems and methods for processing data, and more particularly to systems and methods for channel bit density estimation.

Various embodiments of the present invention provide data processing circuits that include channel bit density (CBD) estimation circuitry. Such CBD estimation circuitry may rely on determining a one half pulse width based upon target values, and estimating CBD based on the one half pulse width. In other cases, the CBD estimation circuitry may rely on up-sampling a Dibit pulse, and calculating an estimated CBD based upon the up-sampled Dibit pulse. This estimated CBD value may then be used for one or more calibrations or characterizations as are known in the art.

This summary provides only a general outline of some embodiments of the invention. The phrases "in one embodiment," "according to one embodiment," "in various embodiments," "in one or more embodiments," "in particular embodiments" and the like generally mean the particular feature, structure, or characteristic following the phrase is included in at least one embodiment of the present invention, and may be included in more than one embodiment of the present invention. Importantly, such phrases do not necessarily refer to the same embodiment. Many other embodiments of the invention will become more fully apparent from the following detailed description, the appended claims and the accompanying drawings.

### BRIEF DESCRIPTION OF THE DRAWINGS

A further understanding of the various embodiments of the present invention may be realized by reference to the figures which are described in remaining portions of the specification. In the figures, like reference numerals are used throughout several figures to refer to similar components. In some instances, a sub-label consisting of a lower case letter is associated with a reference numeral to denote one of multiple similar components. When reference is made to a reference

2

numeral without specification to an existing sub-label, it is intended to refer to all such multiple similar components.

FIG. 1 shows a storage system including a read channel circuit having CBD estimation circuitry in accordance with some embodiments of the present invention; and

FIG. 2 depicts a communication system including a receiver having CBD estimation circuitry in accordance with various embodiments of the present invention;

FIG. 3 depicts a data processing circuit including a coefficient and target calculation circuit in accordance with some embodiments of the present invention;

FIG. 4 shows one implementation of the coefficient and target calculation circuit of FIG. 3 in accordance with various embodiments of the present invention;

FIG. 5 is a flow diagram showing one method in accordance with some embodiments of the present invention for CBD estimation;

FIG. 6 is a flow diagram showing a method in accordance with other embodiments of the present invention for CBD estimation; and

FIG. 7 graphically depicts a pulse from which CBD estimation may be performed in accordance with the methods of both FIG. 6 and FIG. 7.

### DETAILED DESCRIPTION OF SOME EMBODIMENTS OF THE INVENTION

The present inventions are related to systems and methods for processing data, and more particularly to systems and methods for retrying a previously failed data processing.

Various embodiments of the present invention provide data processing circuits that include channel bit density (CBD) estimation circuitry. Such CBD estimation circuitry may rely on determining a one half pulse width based upon target values, and estimating CBD based on the one half pulse width. In other cases, the CBD estimation circuitry may rely on up-sampling a Dibit pulse, and calculating an estimated CBD based upon the up-sampled Dibit pulse. This estimated CBD value may then be used for one or more calibrations or characterizations as are known in the art.

Turning to FIG. 1, a storage system 100 including a read channel circuit 110 having CBD estimation circuitry is shown in accordance with one or more embodiments of the present invention. Storage system 100 may be, for example, a hard disk drive. Storage system 100 also includes a preamplifier 170, an interface controller 120, a hard disk controller 166, a motor controller 168, a spindle motor 172, a disk platter 178, and a read/write head assembly 176 that incorporates a magneto-resistive head. Interface controller 120 controls addressing and timing of data to/from disk platter 178. The data on disk platter 178 consists of groups of magnetic signals that may be detected by read/write head assembly 176 when the assembly is properly positioned over disk platter 178. In one embodiment, disk platter 178 includes magnetic signals recorded in accordance with either a longitudinal or a perpendicular recording scheme.

In a typical read operation, read/write head assembly 176 is accurately positioned by motor controller 168 over a desired data track on disk platter 178. Motor controller 168 both positions read/write head assembly 176 in relation to disk platter 178 and drives spindle motor 172 by moving read/write head assembly to the proper data track on disk platter 178 under the direction of hard disk controller 166. Spindle motor 172 spins disk platter 178 at a determined spin rate (RPMs). Once read/write head assembly 178 is positioned adjacent the proper data track, magnetic signals representing data on disk platter 178 are sensed by read/write head assembly.

3

bly **176** as disk platter **178** is rotated by spindle motor **172**. The sensed magnetic signals are provided as a continuous, minute analog signal representative of the magnetic data on disk platter **178**. This minute analog signal is transferred from read/write head assembly **176** to read channel circuit **110** via preamplifier **170**. Preamplifier **170** is operable to amplify the minute analog signals accessed from disk platter **178**. In turn, read channel circuit **110** decodes and digitizes the received analog signal to recreate the information originally written to disk platter **178**. This data is provided as read data **103** to a receiving circuit. A write operation is substantially the opposite of the preceding read operation with write data **101** being provided to read channel circuit **110**. This data is then encoded and written to disk platter **178**.

During operation, CBD estimation may be performed using a combination of a data set read from disk platter **178** and a corresponding known pattern. Such an approach may be done using circuitry similar to that discussed below in relation to FIG. **3** and FIG. **4**, and/or using the method discussed below in relation to FIG. **6**. Alternatively, the approach may be done using the method discussed below in relation to FIG. **5**.

It should be noted that storage system **100** may be integrated into a larger storage system such as, for example, a RAID (redundant array of inexpensive disks or redundant array of independent disks) based storage system. Such a RAID storage system increases stability and reliability through redundancy, combining multiple disks as a logical unit. Data may be spread across a number of disks included in the RAID storage system according to a variety of algorithms and accessed by an operating system as if it were a single disk. For example, data may be mirrored to multiple disks in the RAID storage system, or may be sliced and distributed across multiple disks in a number of techniques. If a small number of disks in the RAID storage system fail or become unavailable, error correction techniques may be used to recreate the missing data based on the remaining portions of the data from the other disks in the RAID storage system. The disks in the RAID storage system may be, but are not limited to, individual storage systems such as storage system **100**, and may be located in close proximity to each other or distributed more widely for increased security. In a write operation, write data is provided to a controller, which stores the write data across the disks, for example by mirroring or by striping the write data. In a read operation, the controller retrieves the data from the disks. The controller then yields the resulting read data as if the RAID storage system were a single disk.

The data decoder circuit used in relation to read channel circuit **110** may be, but is not limited to, a low density parity check (LDPC) decoder circuit as are known in the art. Such low density parity check technology is applicable to transmission of information over virtually any channel or storage of information on virtually any media. Transmission applications include, but are not limited to, optical fiber, radio frequency channels, wired or wireless local area networks, digital subscriber line technologies, wireless cellular, Ethernet over any medium such as copper or optical fiber, cable channels such as cable television, and Earth-satellite communications. Storage applications include, but are not limited to, hard disk drives, compact disks, digital video disks, magnetic tapes and memory devices such as DRAM, NAND flash, NOR flash, other non-volatile memories and solid state drives.

In addition, it should be noted that storage system **100** may be modified to include solid state memory that is used to store data in addition to the storage offered by disk platter **178**. This solid state memory may be used in parallel to disk platter **178**

4

to provide additional storage. In such a case, the solid state memory receives and provides information directly to read channel circuit **110**. Alternatively, the solid state memory may be used as a cache where it offers faster access time than that offered by disk platter **178**. In such a case, the solid state memory may be disposed between interface controller **120** and read channel circuit **110** where it operates as a pass through to disk platter **178** when requested data is not available in the solid state memory or when the solid state memory does not have sufficient storage to hold a newly written data set. Based upon the disclosure provided herein, one of ordinary skill in the art will recognize a variety of storage systems including both disk platter **178** and a solid state memory.

Turning to FIG. **2**, a communication system **200** including a receiver **220** having digital MRA compensation circuitry is shown in accordance with some embodiments of the present invention. Communication system **200** includes a transmitter **210** that is operable to transmit encoded information via a transfer medium **230** as is known in the art. The encoded data is received from transfer medium **230** by receiver **220**. Transfer medium **230** may be any transfer medium known in the art including, but not limited to, a wireless medium, a wired medium, storage medium, an optical medium, or the like. Based upon the disclosure provided herein, one of ordinary skill in the art will recognize a variety of transfer mediums that may be used in relation to different embodiments of the present invention.

During operation, CBD estimation may be performed using a combination of a data set read from disk platter **178** and a corresponding known pattern. Such an approach may be done using circuitry similar to that discussed below in relation to FIG. **3** and FIG. **4**, and/or using the method discussed below in relation to FIG. **6**. Alternatively, the approach may be done using the method discussed below in relation to FIG. **5**.

Turning to FIG. **3**, a data processing circuit **300** including a coefficient and target calculation circuit **390** is shown in accordance with some embodiments of the present invention. Data processing circuit **300** includes an analog front end circuit **310** that receives an analog input **308**. Analog front end circuit **310** processes analog input **308** and provides a processed analog signal **312** to an analog to digital converter circuit **315**. Analog front end circuit **310** may include, but is not limited to, an analog filter and an amplifier circuit as are known in the art. Based upon the disclosure provided herein, one of ordinary skill in the art will recognize a variety of circuitry that may be included as part of analog front end circuit **310**. In some cases, analog input **308** is derived from a read/write head assembly (not shown) that is disposed in relation to a storage medium (not shown). In other cases, analog input **308** is derived from a receiver circuit (not shown) that is operable to receive a signal from a transmission medium (not shown). The transmission medium may be wired or wireless. Based upon the disclosure provided herein, one of ordinary skill in the art will recognize a variety of sources from which analog input **308** may be derived.

Analog to digital converter circuit **315** converts processed analog signal **312** into a corresponding series of digital samples **317**. Analog to digital converter circuit **315** may be any circuit known in the art that is capable of producing digital samples corresponding to an analog input signal. Based upon the disclosure provided herein, one of ordinary skill in the art will recognize a variety of analog to digital converter circuits that may be used in relation to different embodiments of the present invention. Digital samples **317** are provided to an equalizer circuit **320**. Equalizer circuit **320** applies an equalization algorithm to digital samples **317** to

5

yield an equalized output 322. In some embodiments of the present invention, equalizer circuit 320 is a digital finite impulse response filter circuit as are known in the art.

In addition, digital samples 317 are provided to coefficient and target calculation circuit 390. As more fully discussed below, coefficient and target calculation circuit 390 is operable to calculate target values 394 provided to a data detection and decoding circuit 374, coefficient values 392 provided to equalizer circuit 320, and a CBD estimate 398. The operation of equalizer circuit 320 is at least in part governed by coefficient values 392, and data detection and decoding circuit 374 is at least in part based on target values 394. Data detection and decoding circuit 374 includes a data detector circuit 325, a central queue memory circuit 360, and a data decoder circuit 350. In addition,

Equalized output 322 is provided to both data detector circuit 325 and to a sample buffer circuit 375. Sample buffer circuit 375 stores equalized output 322 as buffered data 377 for use in subsequent iterations through data detector circuit 325. Data detector circuit 325 may be any data detector circuit known in the art that is capable of producing a detected output 327. As some examples, data detector circuit 325 may be, but is not limited to, a Viterbi algorithm detector circuit or a maximum a posteriori detector circuit as are known in the art. Of note, the general phrases “Viterbi data detection algorithm” or “Viterbi algorithm data detector circuit” are used in their broadest sense to mean any Viterbi detection algorithm or Viterbi algorithm detector circuit or variations thereof including, but not limited to, bi-direction Viterbi detection algorithm or bi-direction Viterbi algorithm detector circuit. Also, the general phrases “maximum a posteriori data detection algorithm” or “maximum a posteriori data detector circuit” are used in their broadest sense to mean any maximum a posteriori detection algorithm or detector circuit or variations thereof including, but not limited to, simplified maximum a posteriori data detection algorithm and a max-log maximum a posteriori data detection algorithm, or corresponding detector circuits. Based upon the disclosure provided herein, one of ordinary skill in the art will recognize a variety of data detector circuits that may be used in relation to different embodiments of the present invention. Detected output 327 may include both hard decisions and soft decisions. The terms “hard decisions” and “soft decisions” are used in their broadest sense. In particular, “hard decisions” are outputs indicating an expected original input value, and the “soft decisions” indicate a likelihood that corresponding hard decisions are correct. Based upon the disclosure provided herein, one of ordinary skill in the art will recognize a variety of hard decisions and soft decisions that may be used in relation to different embodiments of the present invention.

Detected output 327 is provided to a central queue memory circuit 360 that operates to buffer data passed between data detector circuit 325 and data decoder circuit 350. In some cases, central queue memory circuit 360 includes interleaving (i.e., data shuffling) and de-interleaving (i.e., data un-shuffling) circuitry known in the art. When data decoder circuit 350 is available, data decoder circuit 350 accesses detected output 327 from central queue memory circuit 360 as a decoder input 356. Data decoder circuit 350 applies a data decoding algorithm to decoder input 356 in an attempt to recover originally written data. Data decoder circuit 350 may be any data decoder circuit known in the art that is capable of applying a decoding algorithm to a received input. Data decoder circuit 350 may be, but is not limited to, a low density parity check (LDPC) decoder circuit or a Reed Solomon decoder circuit as are known in the art. Based upon the disclosure provided herein, one of ordinary skill in the art will

6

recognize a variety of data decoder circuits that may be used in relation to different embodiments of the present invention.

A resulting decoded output 352 is provided from data decoder circuit 350 upon completing application of the data decode algorithm. Similar to detected output 327, decoded output 352 may include both hard decisions and soft decisions. Where the original data is recovered (i.e., the data decoding algorithm converges) or a timeout condition occurs, decoded output 352 is stored to a memory included in a hard decision output circuit 380. In turn, hard decision output circuit 380 provides the converged decoded output 352 as a data output 384 to a recipient (not shown). The recipient may be, for example, an interface circuit operable to receive processed data sets. Based upon the disclosure provided herein, one of ordinary skill in the art will recognize a variety of recipients that may be used in relation to different embodiments of the present invention.

One or more iterations through the combination of data detector circuit 325 and data decoder circuit 350 may be made in an effort to converge on the originally written data set. Processing through both the data detector circuit and the data decoder circuit is referred to as a “global iteration”. In contrast, each pass through the data decoder circuit is referred to as a “local iteration”. For the first global iteration, data detector circuit 325 applies the data detection algorithm to equalized output 322 without guidance from a decoded output. For subsequent global iterations, data detector circuit 325 applies the data detection algorithm to buffered data 377 as guided by decoded output 352. Decoded output 352 is stored to central queue memory circuit 360 as a decoder output 354, and is provided from central queue memory circuit 360 as a detector input 329.

During each global iteration it is possible for data decoder circuit 350 to make one or more local iterations including application of the data decoding algorithm to decoder input 356. For the first local iteration, data decoder circuit 350 applies the data decoder algorithm without guidance from decoded output 352. For subsequent local iterations, data decoder circuit 350 applies the data decoding algorithm to decoder input 356 as guided by a previous decoded output 352. The number of local iterations allowed may be, for example, ten. Based upon the disclosure provided herein, one of ordinary skill in the art will recognize a variety of different numbers of local iterations that may be allowed in accordance with different embodiments of the present invention. Where the number of local iterations through data decoder circuit 350 exceeds that allowed, but it is determined that at least one additional global iteration during standard processing of the data set is allowed, decoded output 352 is provided back to central queue memory circuit 360 as decoded output 354. Decoded output 354 is maintained in central queue memory circuit 360 until data detector circuit 325 becomes available to perform additional processing.

In contrast, where the number of local iterations through data decoder circuit 350 exceeds that allowed and it is determined that the allowable number of global iterations has been surpassed for the data set and/or a timeout or memory usage calls for termination of processing of the particular data set, processing of the data set concludes and the decoded output is provided as data output 352 with an indication that the output is unusable.

In one embodiment of the present invention, coefficient and target calculation circuit 390 is operable to estimate a channel bit density based upon a Dibit pulse. This estimated channel bit density is provided as CBD estimate 398, and used to calculate one or both of target values 394 and coefficient values 392. Target values 394 and coefficient values 392

7

may be calculated base upon the estimated channel bit density using any algorithm or approach known in the art. An example of such a Dibit pulse is shown as pulse **705** of a timing diagram of FIG. 7. In estimating the channel bit density, the received Dibit pulse is up-sampled. The Dibit pulse corresponds to a sampling rate L, and the up-sampled or over-sampling rate is Q where Q is a multiple of L. The over-sampling (OSR) is thus defined by the following equation:

$$OSR=Q/L.$$

Using the over-sampled Dibit pulse (OS\_Pulse), a first estimate of channel bit density (CBD') may be calculated in accordance with the following pseudocode:

---

```

CBD' = 0; //initialize the estimated channel bit density//
For i = 0 to n { //repeat over all samples corresponding to the Dibit
pulse //
    If (OS_Pulse[i] > 0.5 Peak_Pulse){
        CBD' = CBD' + OS_Pulse/Peak_Pulse;
    }
    CBD' = CBD'/OSR.
}

```

---

In the preceding pseudocode, Peak\_Pulse corresponds to the maximum value of OS\_Pulse over the interval for i=0 to i=n samples, and the 0.5 Peak\_Pulse corresponds to the width of the Dibit pulse at the one half peak value. The Peak Pulse corresponds to the "Peak" identified on pulse **700** of FIG. 7, and the 0.5 Peak Pulse corresponds to a width **710** of pulse **700** of FIG. 7.

The first estimate of channel bit density (CBD') may exhibit some offset from an actual channel bit density. In some cases, the channel may be tested to determine the fixed offset by measuring actual channel bit density and comparing it with the first estimate of channel bit density. This fixed offset remains substantially constant over a range of operating conditions. Once established, a second estimate of channel bit density (CBD'') may be calculated in accordance with the following equation:

$$CBD''=CBD'+\text{Fixed Offset.}$$

The second estimate of channel bit density is provided as CBD estimate **398**.

In other embodiments of the present invention, coefficient and target calculation circuit **390** is operable to estimate a channel bit density based upon digital samples **317** and a corresponding known pattern. In some cases, the known pattern is provided to data processing circuit **300**. In other cases, such as that shown in FIG. 3, the known pattern is the converged result from data decoder circuit **350** (decoded output **352**). In this embodiment, digital samples **317** are equalized using an equalizer circuit (not shown) using coefficient values **392** that is substantially the same as equalizer circuit **320** to yield an equalized output (y), and decoded output **352** is processed through a target filter (not shown) using target values **394** to yield a target output (d). The target output (d) is subtracted from the equalized output (y) to yield an error output. Target values **394** and coefficient values **392** are adjusted such that the error value is reduced.

FIG. 4 depicts a calculation circuit **400** that may be used to implement coefficient and target calculation circuit **390** where the channel bit density is estimated based upon digital samples **317** and the corresponding known pattern. Where calculation circuit **400** is used in place of coefficient and target calculation circuit **390**, digital samples **317** are connected to digital samples **402**, decoded output **352** or a

8

received known pattern is connected to ideal output **404**, CBD estimate **398** is connected to a CBD estimate **498**, coefficient values **392** are connected to a coefficient output **492**, and target values **394** are connected to a target output **494**. Calculation circuit **400** includes an equalizer circuit **410** that equalizes digital samples **412** to yield an equalized output **412** (y) using interim coefficients **415** (e.g.,  $[f_0, f_1, f_2, \dots, f_{N-1}]$ ), and a target filter circuit **420** applies a target filtering algorithm to ideal output **404** to yield a target output **422** (d) using interim values **425** (e.g.,  $[1, h_1, h_2, \dots, h_{M-1}]$ ), target output **422** is subtracted from equalized output **412** by a summation circuit **430** to yield an error value **435**.

Error value **435** is provided to a coefficient and target value calculation circuit **440**. Coefficient and target value calculation circuit **440** is operable to calculate updated interim coefficients **415** and interim values **425** to drive error value **435** toward zero. Such calculations are done based upon the following definitions relying on Toeplitz matrices denoted using Matlab™ notation:

$$\vec{y} = T_x \vec{f},$$

$$\vec{d} = T_a \vec{h},$$

$$T_x = \text{Toeplitz}(x(N:\text{end}), x(N:-1:1)), \text{ and}$$

$$T_a = \text{Toeplitz}(a(M:\text{end}), a(M:-1:1)),$$

where  $T_x$  is an array of the samples received as digital samples **402**,  $T_a$  is an array of the values received as ideal output **404**,  $\vec{f}$  are interim coefficients **415** and  $\vec{h}$  is interim values **425**. Based upon the aforementioned definitions, values for both interim coefficients **415** and interim values **425** are calculated to render the following equations true, again using Matlab™ notation:

$$\begin{aligned} \begin{pmatrix} \vec{f} \\ \vec{h}(2:\text{end}) \end{pmatrix} &= T_{x,a} / T_a(:, 1) \\ &= (T_{x,a}^T \cdot T_{x,a})^{-1} \cdot T_a(:, 1) \end{aligned}$$

$$T_{x,a} \equiv [T_x, T_a(:, 2:\text{end})].$$

The resulting values of  $\vec{f}$  are provided as coefficient output **492** and the resulting values of  $\vec{h}$  are provided as target output **494**.

A CBD calculation circuit **450** calculates an estimated channel bit density that is provided as CBD estimate **498**. Calculating the estimated channel bit density relies upon an auto correlation calculated in accordance with the following equation:

$$R(j) = \sum_{i=-N}^N h(i)h(j-1),$$

where N corresponds to the number of samples on either side of a pulse (i.e., the distance from the peak of the pulse) used for the auto correlation. Based upon the calculated auto correlation, a width of the pulse at one half of the peak value (i.e., 0.5 Peak\_Pulse) is determined. From this, an estimated chan-

9

nel bit density ( $CBD_{R(h)}$ ) is calculated in accordance with the following equation:

$$CBD_{R(h)} = \frac{0.5 \text{ Peak\_Pulse}}{T_{bit} \cdot \sqrt{2}},$$

where  $T_{bit}$  is a period of the bit rate at which the medium is read or at which data from the medium is received. This estimated channel bit density is provided as CBD estimate 498.

Turning to FIG. 5, a flow diagram 500 shows one method in accordance with some embodiments of the present invention for CBD estimation. Following flow diagram 500, a Dibit pulse is received (block 505). An example of such a Dibit pulse is shown as pulse 705 of a timing diagram of FIG. 7. The received Dibit pulse is up-sampled (i.e., over sampled) using a sampling clock with a frequency that is some multiple of the bit rate at which a medium is read or at which data from the medium is received (block 510). This up-sampling yields a un-sampled pulse. The Dibit pulse corresponds to a sampling rate L, and the up-sampled or over-sampling rate is Q. The over-sampling (OSR) is thus defined by the following equation:

$$OSR = Q/L.$$

Using the over-sampled Dibit pulse (OS\_Pulse), an estimated channel bit density (CBD') may be calculated in accordance with the following pseudocode:

```

CBD' = 0; //initialize the estimated channel bit density//
For i = 0 to n { //repeat over all samples corresponding to the Dibit
pulse //
    If (OS_Pulse[i] > 0.5 Peak_Pulse){
        CBD' = CBD' + OS_Pulse/Peak_Pulse;
    }
    CBD' = CBD'/OSR.
}

```

(block 515). In the preceding pseudocode, the Peak\_Pulse corresponds to the maximum value of OS\_Pulse over the interval for  $i=0$  to  $i=n$ , and the 0.5 Peak\_Pulse corresponds to the width of the pulse at the one half peak value. The Peak Pulse corresponds to the "Peak" identified on pulse 700 of FIG. 7, and the 0.5 Peak Pulse corresponds to a width 710 of pulse 700 of FIG. 7. The estimated channel bit density (CBD') may exhibit some offset from an actual channel bit density. In some cases, the channel may be tested to determine the fixed offset by measuring actual channel bit density and comparing it with the first estimate of channel bit density. This fixed offset remains substantially constant over a range of operating conditions. Once established, an offset channel bit density (CBD'') may be calculated in accordance with the following equation:

$$CBD'' = CBD' + \text{Fixed Offset}.$$

(block 520).

Turning to FIG. 6, a flow diagram 600 shows a method in accordance with other embodiments of the present invention for CBD estimation. Following flow diagram 600, digital samples are received (block 605) along with a corresponding known pattern (block 610). In some embodiments of the present invention, the digital samples are received from an analog to digital converter circuit that converts a received analog signal to yield the digital samples. The analog signal may be derived from a channel such as, for example, a wireless communication channel, a wired communication chan-

10

nel, a magnetic storage medium, an optical storage medium, or the like. Based upon the disclosure provided herein, one of ordinary skill in the art will recognize a variety of channels from which the analog signal is derived. The corresponding known pattern is the expected result from the channel and may be provided by an external source, or may be derived from the digital samples after data detection and data decoding is applied to the digital samples.

Coefficient ( $\vec{f}$ ) and target ( $\vec{h}$ ) values are calculated based upon the digital samples and the corresponding known pattern (block 615). These calculations may be done by applying an equalizing algorithm to the received digital samples using coefficient values ( $\vec{f} = [f_0, f_1, f_2, \dots, f_{N-1}]$ ), and by applying a target filtering algorithm to the known pattern using target values ( $\vec{h} = [1, h_1, h_2, \dots, h_{M-1}]$ ). Calculating updated values for coefficient ( $\vec{f}$ ) and target ( $\vec{h}$ ) values is done based upon the following definitions relying on Toeplitz matrices denoted using Matlab™ notation:

$$\vec{y} = T_x \vec{f},$$

$$\vec{d} = T_a \vec{h},$$

$$T_x = \text{Toeplitz}(x(N:\text{end}), x(N:-1:1)), \text{ and}$$

$$T_a = \text{Toeplitz}(a(M:\text{end}), a(M:-1:1)),$$

where  $T_x$  is an array of the receive digital samples, and  $T_a$  is an array of the known pattern values. Based upon the aforementioned definitions, updated values coefficient ( $\vec{f}$ ) and target ( $\vec{h}$ ) are calculated to render the following equations true, again using Matlab™ notation:

$$\begin{pmatrix} \vec{f} \\ \vec{h}(2:\text{end}) \end{pmatrix} = T_{x,a} / T_a(:, 1) \\ \equiv (T_{x,a}^T \cdot T_{x,a})^{-1} \cdot T_a(:, 1)$$

$$T_{x,a} \equiv [Tx, Ta(:, 2:\text{end})].$$

The resulting values of  $\vec{f}$  are provided as a coefficient output and the resulting values of  $\vec{h}$  are provided as target output.

A pulse width at half of the peak is calculated based upon the target values ( $\vec{h}$ ) (block 620). An example of a pulse represented by the digital samples is shown as pulse 705 of a timing diagram of FIG. 7, and a pulse width 710 at half of the "peak" is also shown on FIG. 7. The pulse width is calculated based upon an auto correlation calculated in accordance with the following equation:

$$R(j) = \sum_{i=-N}^N h(i)h(j-1),$$

where N corresponds to the number of samples on either side of a pulse (i.e., the distance from the peak of the pulse) used for the auto correlation. Based upon the calculated auto correlation, a width of the pulse at one half of the peak value (e.g., 0.5 PW 710) is determined (block 625). From this, an esti-

## 11

mated channel bit density ( $CBD_{R(h)}$ ) is calculated in accordance with the following equation:

$$CBD_{R(h)} = \frac{\frac{1}{2}PW}{T_{bit} \cdot \sqrt{2}},$$

where  $T_{bit}$  is a period of the bit rate at which the medium is read or at which data from the medium is received (block 630).

It should be noted that the various blocks discussed in the above application may be implemented in integrated circuits along with other functionality. Such integrated circuits may include all of the functions of a given block, system or circuit, or only a subset of the block, system or circuit. Further, elements of the blocks, systems or circuits may be implemented across multiple integrated circuits. Such integrated circuits may be any type of integrated circuit known in the art including, but are not limited to, a monolithic integrated circuit, a flip chip integrated circuit, a multichip module integrated circuit, and/or a mixed signal integrated circuit. It should also be noted that various functions of the blocks, systems or circuits discussed herein may be implemented in either software or firmware. In some such cases, the entire system, block or circuit may be implemented using its software or firmware equivalent. In other cases, the one part of a given system, block or circuit may be implemented in software or firmware, while other parts are implemented in hardware.

In conclusion, the invention provides novel systems, devices, methods and arrangements for limiting the effects of non-linear distortion and/or reducing signal to noise ratio variation. While detailed descriptions of one or more embodiments of the invention have been given above, various alternatives, modifications, and equivalents will be apparent to those skilled in the art without varying from the spirit of the invention. Therefore, the above description should not be taken as limiting the scope of the invention, which is defined by the appended claims.

What is claimed is:

1. A data processing system, the system comprising:
  - a channel bit density estimation circuit, the channel bit density estimation circuit comprising:
    - an equalizer circuit operable to equalize a set of digital samples based upon coefficients to yield and equalized output;
    - a target filter circuit operable to apply a target filter algorithm to a known pattern to yield a target output, wherein the target filter algorithm is governed at least in part by a set of target values; and
    - a channel bit density calculation circuit operable to calculate an estimated channel bit density of a channel from which the digital samples are derived based at least in part on a combination of the equalized output and the target output.
2. The data processing system of claim 1, wherein the system further comprises:
  - a coefficient and target calculation circuit operable to:
    - update the target values based upon a combination of the equalized output and the target output; and
    - update the values of the coefficients based upon the combination of the equalized output and the target output.
3. The data processing system of claim 1, wherein calculating the estimated channel bit density comprises:

## 12

determining a width of the pulse represented by equalized output corresponding to approximately one half of a peak value of the pulse; and  
calculating the estimated channel bit density based on the width.

4. The data processing system of claim 3, wherein determining the width includes calculating an auto-correlation of the set of target values.

5. The data processing system of claim 1, wherein the data processing system is implemented as part of a storage device, and wherein the channel includes a storage medium.

6. The data processing system of claim 1, wherein the data processing system is implemented as part of a communication device, and wherein the channel includes a communication medium.

7. The data processing system of claim 1, wherein the data processing system is implemented as part of an integrated circuit.

8. A data processing system, the system comprising:

- a channel bit density estimation circuit, the channel bit density estimation circuit comprising:

- a means for equalizing a set of digital samples based upon coefficients to yield and equalized output;

- a means for applying a target filter algorithm to a known pattern to yield a target output, wherein the target filter algorithm is governed at least in part by a set of target values; and

- a means for estimating channel bit density based at least in part on a combination of the equalized output and the target output.

9. The system of claim 8, wherein the means for estimating channel bit density is a channel bit density calculation circuit operable to calculate an estimated channel bit density of a channel from which the digital samples are derived based at least in part on the combination of the equalized output and the target output.

10. The data processing system of claim 9, wherein calculating the estimated channel bit density comprises:

- determining a width of the pulse represented by equalized output corresponding to approximately one half of a peak value of the pulse; and

- calculating the estimated channel bit density based on the width.

11. The data processing system of claim 10, wherein determining the width includes calculating an auto-correlation of the set of target values.

12. The data processing system of claim 8, wherein the data processing system is implemented as part of an integrated circuit.

13. The data processing system of claim 8, wherein the data processing system is implemented as part of a communication device, and wherein the channel includes a communication medium.

14. The data processing system of claim 8, wherein the data processing system is implemented as part of a storage device, and wherein the channel includes a storage medium.

15. The data processing system of claim 8, wherein the system further comprises:

- a means for updating the target values based upon a combination of the equalized output and the target output; and

- a means for updating the values of the coefficients based upon the combination of the equalized output and the target output.

16. A method for channel bit density estimation, the method comprising:

using an equalizer circuit, equalizing a set of digital samples based upon coefficients to yield an equalized output;

using a target filter circuit, target filtering a known pattern based upon target values to yield a target output; and  
calculating an estimated channel bit density of a channel from which the digital samples are derived based at least in part on a combination of the equalized output and the target output.

**17.** The method of claim **16**, the method further comprising:

determining a width of the pulse represented by equalized output corresponding to approximately one half of a peak value of the pulse; and  
calculating the estimated channel bit density based on the width.

**18.** The method of claim **17**, wherein determining the width includes calculating an auto-correlation of the set of target values.

**19.** The method of claim **16**, wherein the method further comprises:

updating the target values based upon a combination of the equalized output and the target output; and  
updating the coefficients value based upon the combination of the equalized output and the target output.

**20.** The method of claim **16**, wherein the method is implemented in relation to a device selected from a group consisting of: a communication device, and a storage device.
